

As for 2-aminoisoheptane, it has two chemical forms: 2-amino-6-methylheptane; 2-amino-5-methylheptane; In the supplements there is a form with "6". It is widely used for simple reasons, holds research and costs less. It is believed that DMHA may be a suitable alternative to other stimulants such as BMPEA (acacia rigidula) citrates and AMP for DMAA.

Abstract: **Background:** Octodrine is the trade name for Dimethylhexylamine (DMHA), a central nervous stimulant that increases the uptake of dopamine and noradrenaline. Originally developed as a nasal decongestant in the 1950's, it has recently been re-introduced on the market as a pre-workout and 'fat-burner' product but its use remains unregulated. Our work provides the first observational cross-sectional analytic study on Octodrine as a new drug trend and its associated harms after a gap spanning seven decades. **Methods:** A comprehensive multilingual assessment of literature, websites, drug fora and other online resources was carried out with no time restriction in English, German, Russian and Arabic. Keywords included Octodrine's synonyms and chemical isomers. **Results:** Only five relevant publications emerged from the literature search, with most of the available data on body building websites and fora. Since 2015, Octodrine has been advertised online as "the next big thing" and "the god of stimulants," with captivating marketing strategies directed at athletes and a wider cohort of users. Reported side-effects include hypertension, dyspnoea and hyperthermia. **Conclusions:** The uncontrolled use of Octodrine, its physiological and psychoactive effects raise serious health implications with possible impact on athletes and doping practices. This new phenomenon needs to be thoroughly studied and monitored.

Keywords: octodrine; dimethylhexylamine; DMHA; ambredin; fitness; novel psychoactive substance; performance and image-enhancing drugs; anti-obesity agents; weight loss

1. Introduction

The evolution of trends within drug use has recently been marked by a rapid expansion in the number of commercially-available psychoactive substances [1], with an increased number of young users [2] and relevant psychiatric consequences [3]. This includes both a proliferation of new drugs ('research chemicals' or 'RC's) with a distinct pharmacology and very little associated research evidence

Based on the latest study, "2-aminoisooheptane" and *Aconitum kusnezoffii* appear to be new disguises for illegal or unapproved synthetic stimulants like 1,3-DMAA, 1,3-DMBA, octodrine and the previously unidentified DMAA-analog, 1,4-DMAA (also known as 2-amino-5-methylhexane).

FDA Acts on Dietary Supplements Containing DMHA and Phenibut
