**Metered-Dose Inhaler:  
How to Use with a Spacer**

- 

1. Shake the medicine.
- 

2. Insert the mouthpiece of the inhaler into the rubber-sealed end of the spacer.
- 

3. Breathe all of the air out of your lungs. Then put the spacer into your mouth between your teeth. Make a tight seal around the mouthpiece with your lips.
- 

4. Press the metered-dose inhaler down once to release a spray of medicine. The medicine will be trapped in the spacer. Breathe in slowly and deeply.
- 

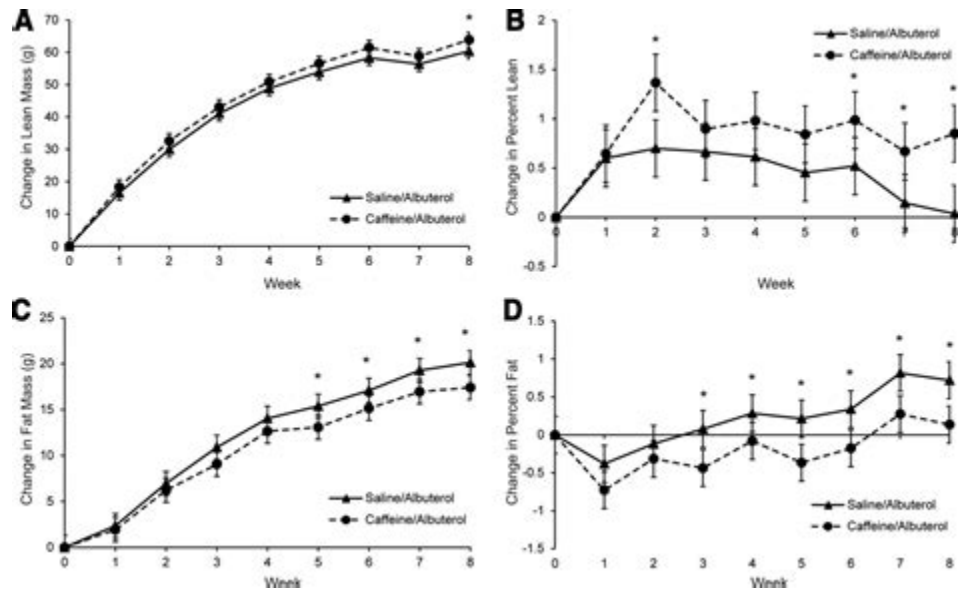

5. Hold your breath for 5 to 10 seconds and then breathe out slowly. If you cannot hold your breath, another method is to breathe in and out slowly for 3 to 5 breaths.

<sup>1</sup>Department of Pediatric Pulmonary Medicine, Connecticut Children's Medical Center, Hartford, CT, USA; <sup>2</sup>Department of Pediatrics, University of Connecticut School of Medicine, Farmington, CT, USA; <sup>3</sup>Division of Pulmonary Medicine, Children's Hospital of Philadelphia, Philadelphia, PA, USA

**Background:** Reversible obstruction on spirometry may be used to diagnose asthma. As per 2005 American Thoracic Society (ATS) guidelines, our pulmonary center began using 360 µg (four puffs) of albuterol rather than 180 µg (two puffs) to determine reversibility on spirometry starting in 2009.

**Hypothesis:** We hypothesized that fewer patients would respond to two puffs of albuterol than four puffs during spirometric testing.

**Methods:** We retrospectively reviewed records from new asthmatics seen in Pediatric Pulmonary Clinic from March 2002 to April 2014 who performed reproducible spirometry. Patients were divided into two groups based on whether they had received two or four puffs of albuterol for bronchodilator assessment. A positive bronchodilator response was defined as an increase of ≥12% in forced expiratory volume in one second (FEV<sub>1</sub>) or ≥25% in forced expiratory flow (FEF<sub>25-75%</sub>). Data were expressed as percentages and mean ± standard error of the mean values. Chi-squared test and Student's *t*-test were utilized.

**Results:** Data were collected for 240 patients; 115 patients received two puffs of albuterol and 125 patients received four puffs. There were no significant differences in baseline characteristics between the two groups. There were no differences following two puffs or four puffs in changes in FEV<sub>1</sub> (10.0±1.1% vs 10.5±1.1% predicted) or FEF<sub>25-75%</sub> (30.2±2.9% vs 33.5±2.9% predicted). Moreover, there was no difference in ATS-defined bronchodilator response between the two groups.

**Conclusion:** Based on the mean change in FEV<sub>1</sub> and overall bronchodilator responsiveness, two puffs of albuterol were not inferior to four puffs in the determination of bronchodilator responsiveness in our pediatric asthmatic patients.

**Keywords:** asthma, reversible obstructive lung disease, pulmonary function testing

### Introduction

Asthma is a common pediatric disease characterized by airflow obstruction, bronchial hyperresponsiveness, and airway inflammation. It is well appreciated that patients' perception of airflow obstruction is highly variable and that medical history and physical examination are not reliable means of characterizing the extent of lung impairment or of excluding other medical conditions.<sup>1</sup> Thus, objective assessments of pulmonary function are necessary. Spirometry, particularly forced expiratory volume in one second (FEV<sub>1</sub>), is considered the gold standard for the evaluation of airway obstruction, and the presence of reversible obstruction on spirometry following short-acting bronchodilator administration may be used to assist in the diagnosis of asthma.<sup>1</sup>

Albuterol is the commonest drug used in bronchodilator assessments. For determining bronchodilator responsiveness in our center, we had routinely given patients the
