Nandrolone

ABSTRACT

We investigated the influence of long-term treatment with supraphysiological doses of an anabolic-androgenic steroid on the Bezold-Jarisch reflex (BJR) control of heart rate (HR) and diastolic arterial pressure (DAP), and whether this treatment induced cardiac hypertrophy. Male rats were treated with nandrolone decanoate (ND) (10 mg kg⁻¹ body weight for 8 weeks; DECA) or vehicle (control animals; CON). After 8 weeks of treatment, the BJR was evaluated by bradycardia and hypotension responses that were elicited by serotonin administration (2–32 µg kg⁻¹). Mean arterial pressure (MAP) was assessed and cardiac hypertrophy was determined by the ratio of the left and right ventricle weight/body weight (LVW/BW and RVW/BW, respectively) and by histological analysis. Total body protein (TBP) content was also evaluated. Nandrolone decanoate treatment increased MAP (CON = 99 ± 1 mmHg; DECA = 109 ± 2 mmHg; *p* < 0.01) but did not change the mean basal HR (CON = 356 ± 11 bpm; DECA = 367 ± 11 bpm). The treatment also induced LV and RV hypertrophy (LVW/BW: CON = 1.86 ± 0.04 mg g⁻¹, DECA = 2.17 ± 0.04 mg g⁻¹, *p* < 0.01; RVW/BW: CON = 0.42 ± 0.02 mg g⁻¹, DECA = 0.53 ± 0.03 mg g⁻¹, *p* < 0.05) and reduced the number of myocyte nuclei/high-power field (CON = 23.0 ± 2; DECA = 9.4 ± 1.0; *p* < 0.01). ND treatment blunted the HR and DAP decreases induced by serotonin. ND determines an increase in the TBP content in DECA group (35 ± 3%; *p* < 0.01) compared with control animals (38 ± 1%). We conclude that 8 weeks of ND treatment induces anabolic effect, cardiac hypertrophy and an elevation of MAP. This treatment also reduces the sensitivity of the BJR control of bradycardia and blood pressure, possibly due to cardiac hypertrophy. The blunted BJR response could contribute to the MAP elevation in DECA animals.

1. Introduction

Anabolic-androgenic steroids (AAS), despite their clinical applications [1], induce adverse effects in competitive athletes, noncompetitive recreational bodybuilders, and even non-athletes who use them for cosmetic purposes rather than to enhance sports performance [2,3]. AAS can induce adverse cardiovascular effects, including hypertension, left ventricular hypertrophy (LVH), impaired diastolic filling, arrhythmia, erythrocytosis, altered lipoprotein pro-

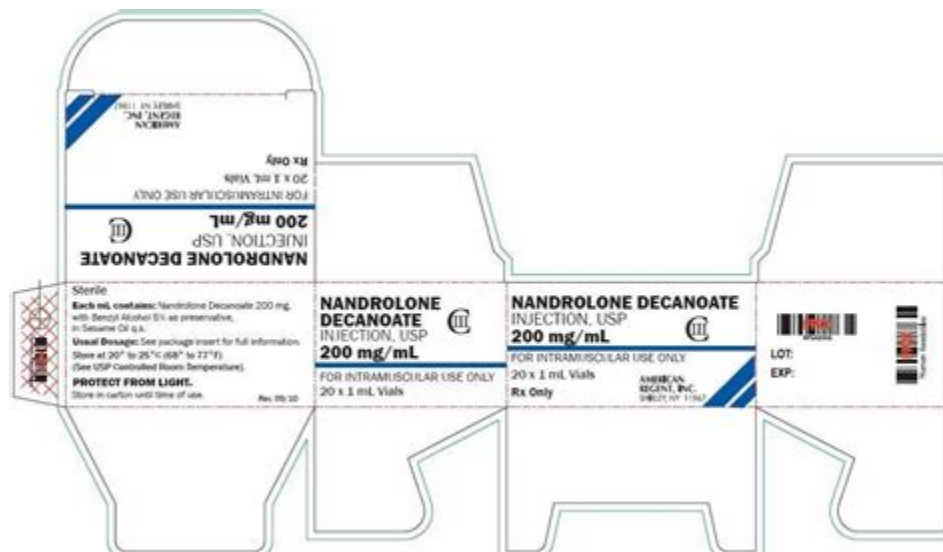

files, and thrombosis [4,5]. In addition, abnormalities in vascular reactivity [6–11] and cardiovascular reflex control of the cardiovascular system [12–16] are also observed under AAS influence.

Ammar et al. [7] showed that the abuse of AAS in presence of hypercholesterolemia can enhance atherogenicity and vasospasm as well as attenuation of vasorelaxation in rabbits. Cunha et al. [9] observed that nandrolone treatment blocks the vascular subsensitivity of aorta to phenylephrine promoted by anaerobic physical training, probably because this hormone decreases NO vasodilating effect and enhances blood concentration of low-density lipoprotein (LDL), damaging the endothelial function of trained animals. In humans, bodybuilders using AAS showed a reduction in endothelial-independent vasodilatation, together with reduced high-density lipoprotein (HDL) concentrations and increased prothrombotic risk, compared with non-users and ex-users

[31] Dosages[edit] A dosage of nandrolone decanoate of 25 to 50 mg once every 6 to 12 weeks (working out to an average exposure of about 2 to 8 mg per week) by intramuscular injection is considered to be appropriate for general androgen replacement therapy in women.
