AND RICHARD CASABURI, Ph.D., M.D.

ABSTRACT

Background Athletes often take androgenic steroids in an attempt to increase their strength. The efficacy of these substances for this purpose is unsubstantiated, however.

Methods We randomly assigned 43 normal men to one of four groups: placebo with no exercise, testosterone with no exercise, placebo plus exercise, and testosterone plus exercise. The men received injections of 600 mg of testosterone enanthate or placebo weekly for 10 weeks. The men in the exercise groups performed standardized weight-lifting exercises three times weekly. Before and after the treatment period, fat-free mass was determined by underwater weighing, muscle size was measured by magnetic resonance imaging, and the strength of the arms and legs was assessed by bench-press and squatting exercises, respectively.

Results Among the men in the no-exercise groups, those given testosterone had greater increases than those given placebo in muscle size in their arms (mean [\pm SE] change in triceps area, 424 ± 104 vs. -81 ± 109 mm²; $P < 0.05$) and legs (change in quadriceps area, 607 ± 123 vs. -131 ± 111 mm²; $P < 0.05$) and greater increases in strength in the bench-press (9 ± 4 vs. -1 ± 1 kg, $P < 0.05$) and squatting exercises (16 ± 4 vs. 3 ± 1 kg, $P < 0.05$). The men assigned to testosterone and exercise had greater increases in fat-free mass (6.1 ± 0.6 kg) and muscle size (triceps area, 501 ± 104 mm²; quadriceps area, 1174 ± 91 mm²) than those assigned to either no-exercise group, and greater increases in muscle strength (bench-press strength, 22 ± 2 kg; squatting-exercise capacity, 38 ± 4 kg) than either no-exercise group. Neither mood nor behavior was altered in any group.

Conclusions Supraphysiologic doses of testosterone, especially when combined with strength training, increase fat-free mass and muscle size and strength in normal men. (N Engl J Med 1996;335:1-7.)

©1996, Massachusetts Medical Society.

ANABOLIC-ANDROGENIC steroids are widely abused by athletes and recreational bodybuilders because of the perception that these substances increase muscle mass and strength,^{1,2} but this premise is unsubstantiated. Testosterone replacement increases nitrogen retention and fat-free mass in castrated animals and hypogonadal men,³⁻⁵ but whether supraphysiologic doses of testosterone or other anabolic-androgenic steroids augment muscle mass and strength in normal men is unknown.^{3,6} Studies of the effects of such steroids on muscle strength have been inconclusive,⁷⁻⁹ and several reviews have emphasized the shortcomings of the studies.^{2,3,8,10} Some of the studies were not randomized; most did not control for intake of energy and protein; the exercise stimulus was often not standardized; and some studies included competitive athletes whose motivation to win may have kept them from complying with a standardized regimen of diet and exercise.

We sought to determine whether supraphysiologic doses of testosterone, administered alone or in conjunction with a standardized program of strength-training exercise, increase fat-free mass and muscle size and strength in normal men. To overcome the pitfalls of previous studies, the intake of energy and protein and the exercise stimulus were standardized. Because some previous studies had demonstrated significant increases in muscle strength and hyper-
