

A cycle of steroids completely changes the functioning of your natural hormone system. You might stop producing natural testosterone altogether. One of the big goals of post-cycle therapy is to get your hormone balance back on track. Post-cycle therapy (PCT) is a critical action to take and one that deserves just as much thought and planning as .

I've been thinking of using tamoxifen to boost my testosterone levels. The reduced estrogen levels would produce less negative feedback inhibition to the HPTA, thus leading to increased testosterone

production. I've found a few studies that confirm this (see below for links). But only one abstract I found mentions the degree of increased T: about a 150% increase in total and free T (in 9 .

Estrogen Blockers for Men: Everything You Need to Know - Verywell Health

Testosterone therapy has various risks, including: Worsening sleep apnea — a potentially serious sleep disorder in which breathing repeatedly stops and starts. Causing acne or other skin reactions. Stimulating noncancerous growth of the prostate (benign prostatic hyperplasia) and growth of existing prostate cancer.

Buy Generic Nolvadex 10/20/40/50mg Tamoxifen

Yes and no: Nolvadex, aka tamoxifen is a very weak estrogen. In men it will make the brain think you have too little estrogen so the brain asks the testicles to make more testosterone that can be converted into estrogen later. In men and women, tamoxifen will block estrogen which can help treat breast cancer.

Can Nolvadex increase testosterone levels?

Tamoxifen is indicated as adjuvant therapy for women with ER-positive early breast cancer (Early Breast Cancer Trialists' Collaborative Group, 1998) as well as hormone-responsive locally advanced and metastatic breast cancer (Buchanan et al . , 1986; Ingle et al . , 1986).

Aromatase inhibitors in men: effects and therapeutic options

Willem de Ronde¹ and Frank H de Jong^{2*}

Abstract

Aromatase inhibitors effectively delay epiphyseal maturation in boys and improve testosterone levels in adult men. Therefore, aromatase inhibitors may be used to increase adult height in boys with gonadotropin-independent precocious puberty, idiopathic short stature and constitutional delay of puberty. Long-term efficacy and safety of the use of aromatase inhibitors has not yet been established in males, however, and their routine use is therefore not yet recommended.

Background

Over the past 15 years it has become evident that in men estradiol is responsible for a number of effects originally attributed to testosterone. Estradiol has an important role in gaining and maintaining bone mass, closing of the epiphyses and the feedback on gonadotropin secretion. This fact became particularly evident in men with aromatase deficiency. Aromatase is the enzyme responsible for conversion of androgens to estrogens. Men with estrogen deficiency caused by a mutation in the CYP19 gene suffer from low bone mineral density (BMD) and unfused epiphyses, and have high gonadotropin and testosterone levels [1]. Estrogen excess in turn has been associated with premature closure of the epiphyses, gynecomastia and low gonadotropin and testosterone levels. Lowering estrogen levels in men has emerged, consequently, as a potential treatment for a number of disorders including pubertas praecox, the andropause (also referred to as late-onset hypogonadism) and gynecomastia. Aromatase inhibitors were proven to be safe, convenient and effective for the treatment of hormone sensitive breast cancer in women although their use is associated with a modest increase in bone resorption [2,3]. This review will discuss the potential targets and the evidence for the use of aromatase inhibitors in men and adds more recent data to the text of an earlier review on this subject [4].

Metabolism of estrogens in men

Aromatase, also known as estrogen synthetase, is the key enzyme in estrogen biosynthesis. The enzyme, localized in the endoplasmic reticulum of the estrogen-producing cell, is encoded by the *CYP19A1* gene. This gene is a member of the *CYP* gene family, encoding a class of enzymes active in the hydroxylation of endogenous and exogenous substances. The *CYP19A1* gene is localized on chromosome 15 and comprises nine exons; the start codon for translation is located on exon 2. Transcription of the aromatase gene is regulated by several tissue-specific promoters. These promoters are under the influence of different hormones and growth factors such as gonadotropins (gonadal promoter I) and interleukin-6, interleukin-11 and tumor necrosis factor- α (adipose/bone promoter I.4; for review see [5]). Aromatase activity has not only been demonstrated in gonads and placenta but also in brain [6], fat tissue [7,8], muscle [9], hair [10], bone [11] and vascular tissue [12].

Estradiol is the most potent estrogen produced in the body. It is synthesized from testosterone or estrone via aromatase or 17 β -hydroxysteroid dehydrogenase, respectively. The total estradiol production rate in the human male has been estimated to be 35-45 μ g (0.130-0.165 μ mol) per day, of which approximately 20% is directly produced by the testes [13,14]. Roughly 60% of circulating estradiol is derived from direct testicular secretion or from conversion of testicular androgens. The remaining fraction is derived from peripheral conversion of adrenal androgens [15]. The mean estradiol plasma concentration in men is only about 1/200 of the mean plasma testosterone concentration [16] and is
