

Flagging occurs when there is too much space between the fabric and the needle plate, which causes the material to bounce up and down, as the needle penetrates through the fabric. This causes the needle to bend and eventually break. With space, there is a greater chance for the needle to flex (bend) and miss the needle hole.

Case report: surgical removal of a migrated needle in right ventricle of an intravenous drug user

Xianming Fu¹, Kai Chen², Xiaobo Liao³ and Kangjun Shen^{4*}

Abstract

Background: Illicit drug use has become an increasing public health and social concern in the past decades worldwide. Intravenous injection has an elevated risk of infection. Needle embolism is a rare complication of intravenous drug users. Retained broken needles can lead to local complications, such as infection, but they also have the potential to embolize to heart or lung, and lead to serious complications.

Method: We reported a rare case of an intravenous drug user which a retained broken needle fragments in the inferior wall of the right ventricle.

Results: We performed a successful surgery and give our comments and recommendations for illicit drug use worldwide and in China.

Conclusions: Illicit Drug use becomes a global problem because of its health and social harmfulness. To help drug addicts and provide prevention and treatment services are the obligations and responsibilities of all medical workers.

Keywords: Surgery, Migrated needle, Illicit drug abuse, Drug rehabilitation treatment

Background

Illicit drug use has attracted more social concern and become a public health concern in the past decades worldwide. Intravenous drug users has a higher risk of infection. Needle embolism, as a rare complication of intravenous drug users [1], can lead to local complications, such as infection. Retained broken needles have the potential to become the emboli in heart or lung, and lead to serious complications. Here we reported a rare case which a retained broken needle fragment in the inferior wall of the right ventricle, we performed a successful surgery and give our comments and recommendations for illicit drug use in China.

Methods and results

A 40-year-old man presented to the emergency department after a needle broke in his right groin while taking heroin intravenously 20 days ago. There were neither special

symptoms nor evidence of infection or infarction. Vital signs and electrocardiogram were normal, and he was hepatitis C virus (HCV) positive, a heavy user of heroin and cocaine over 20 years. Transthoracic echocardiography revealed a retained needle fragment in the inferior wall of the right ventricle (Fig. 1a), and no detectable pericardial effusion. Computed tomography confirmed the location of a needle in the inferior wall of the right ventricle and near the ventricular septum (Fig. 1b and c). Emergency open-heart surgery through a median sternotomy under cardiopulmonary bypass was performed. Chest roentgenogram was performed by the moving bedside X-ray machine in the operation room to rule out unsuspected migration of the needle during patient positioning before proceeding with an incision. The needle was found and removed from the inferior wall of the right ventricle (Fig. 1d and e). The patient recovered uneventfully after the surgery and was discharged home on postoperative day 6.

Discussion

Needle embolism is an infrequent complication of intravenous drug users (IDUs) [1]. Broken needles occur
