GHG Cycle (Human Growth Hormone Guide) - Steroid Cycles

Growth hormone is very useful for experienced steroid users who have achieved a high level of physique enhancement and where further growth or progress seems to have come to a halt using steroids. The addition of GHG can propel the advanced bodybuilder beyond existing limits when used in combination with powerful steroids.

The above Human Growth Hormone doses represent the most common and safest but many, especially those who are physique minded such as bodybuilders will use higher doses. In order to promote true lean muscle mass growth, most men will need at minimum 6-8iu's per day for an extended period of time, and this is assuming they are using high. Fortunately, the abuse of growth hormone is limited by its cost and the fact that anabolic steroids are simply more enticing to the athlete. There are, however, significant potential adverse effects regarding its use that can be best understood by studying known growth hormone excess, as demonstrated in the acromegalic syndrome.

Human Growth Hormone Doses - steroid.com

No, HGH is a peptide hormone, not a steroid. A peptide is a substance from two or more amino acids. People often confuse human growth hormone (HGH) with other substances that can improve athletic ability, but HGH is not a steroid. Some athletes combine HGH with prohibited substances, like anabolic steroids, to try to enhance their performance.

Human Growth Hormone preparations have also been shown to be more effective in maintaining lean muscle mass. It is for this reason that HGH is typically included in post-cycle therapy to help in the prevention of muscle tissue loss secondary to using anabolic steroids as a replacement for endogenous testosterone.
