Abstract: Selective Androgen Receptor Modulators (SARMs) are not FDA approved, and obtaining SARMs for personal use is illegal. Nevertheless, SARM use is increasingly popular amongst recreational athletes. Recent case reports of drug-induced liver injury (DILI) and tendon rupture raise serious concerns for the safety of recreational SARM users. On 10 November 2022 PubMed, Scopus, Web of Science, and ClinicalTrials.gov were searched for studies that reported safety data of SARMs. A multi-tiered screening approach was utilized, and any study or case report of generally healthy individuals exposed to any SARM was included. Thirty-three studies were included in the review with 15 case reports or case series and 18 clinical trials (total patients N = 2136 patients, exposed to SARM N = 1447). There were case reports of drug-induced liver injury (DILI) (N = 15), Achilles tendon rupture (N = 1), rhabdomyolysis (N = 1), and mild reversible liver enzyme elevation (N = 1). Elevated alanine aminotransferase (ALT) was commonly reported in clinical trials in patients exposed to SARM (mean 7.1% across trials). Two individuals exposed to GSK2881078 in a clinical trial were reported to have rhabdomyolysis. Recreational SARM use should be strongly discouraged, and the risks of DILI, rhabdomyolysis, and tendon rupture should be emphasized. However, despite warnings, if a patient refuses to discontinue SARM use, ALT monitoring or dose reduction may improve early detection and prevention of DILI.

1. Introduction

Selective Androgen Receptor Modulators (SARMs) are non-steroidal compounds with favorable oral bioavailability that were developed in the early 2000s in an attempt to overcome the pharmacologic and pharmacokinetic limitations of steroidal androgen receptor agonists (i.e., testosterone and DHT), which have known associations with liver and heart disease [1]. SARMs have been trialed as a pharmacologic intervention to improve a wide variety of conditions such as cancer-associated morbidity, deconditioning after hip fracture, stress incontinence, and benign prostatic hyperplasia [2]. Solomon et al. provided a comprehensive review of current clinical applications [3]. Despite a strong warning from the Food and Drug Administration (FDA) [4], SARM abuse is increasingly popular amongst recreational and professional athletes as a perceived means to improve performance [5]. The prevalence of SARM abuse is uncertain; however, estimates of the global lifetime prevalence rate for use of anabolic-androgenic steroids are 3.3%, with a prevalence rate of 6.4% in males and 1.6% in females [6]. According to a British Army survey of 3168 soldiers

Lawless labs. Friend picked some up from supp store in Orlando area. I told him if legit the s23 is going to kill his test. Adverse effects and potential benefits among selective androgen receptor modulators users: a cross-sectional survey

Iakov V. Efimenko^{1,2}, David Valancy¹, Justin M. Dubin¹ and Ranjith Ramasamy¹

Selective androgen receptor modulators (SARMs) are a class of androgen receptor ligands that bind androgen receptors and display tissue selective activation of androgenic signaling. SARMs have selective anabolic effects on muscle and bone, and were originally synthesized for treatment of muscle wasting conditions, osteoporosis, breast cancer. To date, no SARM has been clinically approved and little is known about the beneficial effects and other adverse effects on users. We examined the adverse effects and potential benefits of SARMs amongst users. We performed an internet survey assessing the demographics of users via a 32-question survey. Using reddit as a platform, we distributed the survey through various subreddits that included potential SARMs users. Out of the 520 responses, 343 participants admitted having used SARMs. Most were males (98.5%), between the ages of 18–29 (72.3%). More than 90% of users acquired SARMs via the internet and did not consult with a physician. More than half of SARMs users experienced side effects including mood swings, decreased testicular size, and acne. More than 90% of men reported increased muscle mass and were satisfied with their SARMs usage. Despite having seemingly positive effects, more than 50% of SARMs users report significant adverse effects. Chi square was the main method of statistical analysis. Future studies should focus on comprehensive reproductive evaluation of men using SARMs.

UJR: Your Sexual Medicine Journal (2022) 34:757–761; <https://doi.org/10.1038/s41443-021-00465-0>

INTRODUCTION

Selective androgen receptor modulators (SARMs) are a class of androgen receptor ligands that bind androgen receptors and display tissue-selective activation of androgenic signaling. The initial efforts to develop steroidal SARMs, based on modifications of the testosterone molecule, date back to the 1940s [1]. In recent years, Ligand Pharmaceuticals were the first to develop a SARM with anabolic activity on skeletal muscle and some degree of tissue selectivity. Two decades since these early efforts, we have witnessed the emergence of a large number of nonsteroidal SARMs from virtually all major pharmaceutical companies but there has been little success in bringing an FDA approved product to market [2]. Furthermore, the success of SERMs such as clomiphene, which now plays an important role in treating both male and female infertility, has reignited interest in SARMs [3].

SARMs with selective anabolic effects on muscle and bone were originally synthesized for treatment of muscle wasting conditions, osteoporosis, breast cancer, and prostate cancer [4]. Such therapeutic compounds were designed to have similar effects to anabolic agents but with reduced androgenic properties. These properties, unfortunately, make SARMs highly attractive for doping in sporting events as well as for illegal bodybuilding use by adolescents and young adults. Prior to 2019, these novel therapeutic compounds were being sold legally over the counter in many supplement stores across United States, as well as various internet portals [5, 6]. Furthermore, concerns about the safety of these products were validated by a study in 2013 in which one of the commonly abused SARMs, ligandrol, was shown to have a

dose-dependent suppression of total testosterone, SHBG, HDL, TG, FSH, LH [7]. Despite being banned by the US Congress in 2019, SARMs continue to be sold on many internet portals, easily sourced as “research compounds not intended for human consumption” and are widely available to the public [8]. Although SARM usage in the treatment of cachexia, BPH, hypogonadism, breast cancer, and prostate cancer seems promising, no SARM to date has received full clinical approval [9].

While SARMs are known to modify androgen receptors, little is known about the effects they may have on the fertility or other adverse effects of its users; there is an urgent need for an investigation. Furthermore, to our knowledge, there has been no study assessing the demographics of people who recreationally use SARMs. Because of the wide availability of these compounds via various internet portals, we hypothesized that many younger individuals are able to get access to these powerful and potentially dangerous compounds. Therefore, we examined the adverse effects among SARMs users in a cross-sectional online survey using Reddit.

MATERIALS AND METHODS

We performed an internet-based survey assessing the demographics of SARMs users via 32 question online survey on Qualtrics. Qualtrics XM is a user experience management software program licensed under University of Miami, which allows users to create and distribute surveys. Reddit is a social news aggregation, web content rating, and discussion website, and it claims to be the “front-page of the internet”. As of February 2021, reddit analytics reported 430 million active users [10]. In our project we used
