Abstract

Selective androgen receptor modulators (SARMs) are a class of nonsteroidal drugs that are favored over anabolic androgenic steroids (AASs) for their tissue-selectivity and improved side-effect profile. These drugs have been evaluated for treatment of various diseases including muscle-wasting disorders, osteoporosis, and breast cancer. Despite lacking approval for therapeutic use, SARMs are widely used recreationally as performance enhancing drugs by bodybuilders and athletes. In recent years, cases of drug-induced liver injury (DILI) secondary to SARMs have begun to emerge, but little is known regarding their hepatotoxicity. In this review, we provide current knowledge regarding DILI from SARMs. A literature search was conducted regarding SARMs and liver injury to evaluate relevant cases and information. SARMs have been associated with a cholestatic syndrome congruent with that of DILI from AASs, and it consists of a bland cholestasis in which there is minimal bile duct injury, inflammation, or necrosis. Patients present with an insidious onset of jaundice with marked hyperbilirubinemia and mild hepatic enzyme elevations. No clear treatment exists, although patients typically show improvement with cessation of the offending SARM. Given the novelty of these drugs, further study is necessary to understand diagnosis, management, and complications of SARM-related DILI.

similar anabolic effects as that of anabolic androgenic steroids (AASs) but with an improved safety profile and reduced androgenic side effects. Since their development, SARMs have been investigated for a wide variety of clinical applications including muscle-wasting diseases, osteoporosis, and breast cancer.¹

These drugs offer greater therapeutic promise than AASs because of their tissue-selective action, metabolic properties, and oral bioavailability.² Like AASs, SARMs act as agonists of the androgen receptor on target tissues such as skeletal muscle and bone. However, in contrast to AASs, SARMs have decreased activity on nontargeted tissues such as the heart, prostate, and liver.¹ Additionally, lack of the 5 α -reductase metabolism of SARMs prevents androgenic side effects such as virilization, androgenic alopecia, or prostatic hyperplasia.²⁻⁵ Furthermore, many AASs cannot be delivered orally because of rapid hepatic clearance.^{5,6} That has led to the development of 17 α -alkylated AASs which reduce hepatic metabolism but increase the risk of liver toxicity.⁷ Conversely, SARMs have been developed with good oral bioavailability and are presumed to have reduced hepatotoxicity;^{8,9} however, that may not be the case.

To date, no SARM has achieved US Food and Drug Administration (FDA) approval;¹⁰ however, a number of SARMs are currently undergoing clinical trials.¹¹ Despite the lack of approval, SARMs have made their way into the world of muscle and performance enhancement. They substances are widely and illicitly distributed online where they are sought after for their anabolic properties and favorable side-effect profile.¹⁻¹² With the growing popularity of SARM use, the FDA has issued a warning against recreational use because of health risks including myocardial infarction, stroke, and notably, liver toxicity.¹³

As these substances have gained popularity, cases of drug-induced liver injury (DILI) secondary to illicit SARM use have begun to emerge.^{14,15} Little is known regarding the overall risks of these substances or their effects on the liver as no SARM has completed appropriate safety investigations.¹¹ With these emerging concerns of hepatotoxicity, increased awareness is necessary to promote recognition of SARMs as a potential etiology of DILI. Additionally, further clinical knowledge among healthcare providers would allow them to counsel patients on the risks posed by recreational SARM use.

At this time, knowledge regarding SARM-related DILI is sparse; and to date, there is no specific information regarding SARMs on major hepatotoxicity databases such as LiverTox.¹⁶ In this review, we discuss background information, current knowledge, and limitations in the understanding of hepatotoxicity secondary to SARMs.
