Dianabol, (sometimes known as dbol) is a concentrated form of Methandrostenolone – which is derived from testosterone. Dianabol is one of the most popular steroids because of its potency and ability to help bodybuilders bulk up quickly, but the side effects are also pretty hard-going. Turinabol, on the other hand, is an adapted version of dbol.

## Low sex drive in women - Symptoms and causes - Mayo Clinic

Does Dianabol affect libido? Bodybuilders and athletes who use Metandienone find that it can have a negative impact on their sex drive. This primarily stems from the suppressive nature of powerful exogenous androgens like dbol to natural testosterone production in the body.

Conclusions. The long-term impact of high dose AAS use on sexual function remains poorly defined. Although high T dosages appeared to be protective of erectile function during use, de novo symptoms such as decreased libido and ED occurred more frequently after discontinuing T, particularly among those using more frequently and for longer durations. . Given the importance of these findings .

### ABSTRACT

**Background:** Female users of anabolic-androgenic steroids (AAS) are at risk of developing masculinizing side effects. This study explores how the development of masculinizing effects has been experienced and processed by women with current or previous AAS use.

**Methods:** Individual, semi-structured interviews were undertaken among 16 current or previous AAS-using women. The interviews were recorded, transcribed verbatim and thematically analyzed.

**Results:** Almost all of the women were introduced to AAS and advised about what substance(s) to use, how much to use and how to use it by a trusted male partner, friend or coach. For some, AAS initiation was an impulsive choice, while others wanted to overcome stagnation and/or prepare for fitness competitions. Many were unprepared for the unwanted masculinizing effects, but some experienced these to be outweighed by the desired effects. Masculinizing effects that could be mediated by hair removal or breast implants were easier to process than a deepened voice. As very few women were open with others about their AAS use, the voice change could disclose use and was often accompanied by feelings of shame and regret. Absence of menstruation and its return following cessation were used to monitor effect, normal function and safety when deciding when to start a new cycle. Clitoral enlargement gave rise to shame and reduced self-esteem, but negative emotions could be reduced by a positive partner response. Increased libido was common and gave rise to positive and negative experiences, depending on life situation, partner status, whether the partner used AAS simultaneously and whether genital changes had also been experienced.

**Conclusion:** Women who use AAS are at risk of developing irreversible masculinizing effects that are difficult to process and that may negatively influence self-esteem, social life and sexual function, both during and after use. More gender-specific information about women and AAS use is needed.

### Background

Anabolic-androgenic steroids (AAS) are synthetic variations of the male sex hormone testosterone, with a capacity to increase muscle volume, strength and male sex characteristics (Kücman, 2008). Due to the masculinizing effects of these substances, they are foremost used by men (Sagoe, Moldé, Andreassen, Turheim & Pallesen, 2014), as well as by some female bodybuilders striving for muscle that is difficult for women to achieve without hormonal preparations (Andreassen & Johannson, 2019). During recent decades, we have seen the female body ideal changing from slim to muscular and strong (Tiggemann & Zaccardo, 2018; Van Hout & Hearne, 2016), which has propagated AAS use in other fitness disciplines and the 'gym culture' in general (Andreassen & Johannson, 2019).

As for men, the most common motivations to use AAS among women are to increase muscle mass and strength, and to reduce body fat (Abraham, Félix Souza, de Souza, Santos & Bahrke, 2017; Ip et al.,

2010). In addition, some women have reported that AAS use was motivated by a wish to increase self-protection abilities following an experience of sexual trauma (Gruber & Pope Jr, 1999). Nonetheless, use of AAS in supraphysiological doses comes with a risk of developing mental (Gruber & Pope Jr, 2000; Piacentino et al., 2015) and physical side effects (Hoerwitz, Andersen & Dalhoff, 2019; Pope et al., 2014). In addition, women are at risk of developing undesired masculine traits, such as increased facial and body hair, deeper voice, reduced breast volume, enlarged clitoris and gonadal dysfunction resulting in irregular or absent menstruation and reduced fertility (Eklöf, Thurelius, Garle, Rane & Sjöqvist, 2003; Franke & Berendonk, 1997; Gruber & Pope Jr, 2000; Nieschlag & Verona, 2015; Strauss, Liggert & Lanese, 1985).

AAS use among women is an under-researched area, and most studies that explore aspects of such use are based on small samples of women who compete in fitness, body building and strength sports (Abraham et al., 2017; Björjesson, Gårsvik, Dahl, Rane & Ekström, 2016; Grogan, Shepherd, Evans, Wright & Hunter, 2006; Gruber &
