Effects and side-effects

The activity of boldenone is mainly anabolic, with a low androgenic potency.

Boldenone will increase nitrogen retention, protein synthesis, increases appetite and stimulates the release of erythropoietin in the kidneys.

Boldenone was synthesized in an attempt to create a long-acting injectable methandrostenolone (Dianabol), for androgen deficiency disorders. Boldenone acts similar to methandrostenolone with less adverse androgenic effects. It has a very long half-life, and can show up on a steroid test for up to 5 months, due to the long undecylenate ester attached to the parent steroid. Trace amounts of the drug can easily be detected for months after discontinued use.

Although commonly compared to nandrolone, boldenone lacks progesterone receptor interaction and all the associated progestogenic side effects.

Boldenone undecylenate - Wikipedia

Anabolic androgenic steroids (AAS) are synthetic derivatives of the male testosterone hormone that have been modified to improve their anabolic rather than androgenic activity (Shahidi 2001). The anabolic effects of AAS promote protein synthesis, muscle growth and erythropoiesis (Mottram & George 2000). Hence, AAS are used to enhance strength and durability of canine, equine and human athletes .
