### Abstract

**Background:** Clomiphene Citrate may be used off-label to treat men with secondary hypogonadism. More commonly used and approved are the exogenous testosterone products such as gels, patches, and injectables. One drawback may be the high levels of serum testosterone (TT) achieved with exogenous products. A single isomer of Clomiphene citrate, Enclomiphene citrate, is in development and may be useful and gain regulatory approval. An open question is whether men using Enclomiphene citrate will experience high levels of TT.

**Aims:** In our efforts to evaluate Enclomiphene citrate as an oral therapy for normalizing testosterone, we conducted a Phase I pilot clinical study (ZA-002: An Open Label, Fixed Dose, Single Center, Phase I Study to Evaluate the Changes in Total Testosterone with Oral Administration of Enclomiphene Citrate in Healthy Men with Low and Normal Testosterone) to assess the compound's effects on TT.

**Methods:** Sixteen men, mean age 46, with low or normal testosterone levels were enrolled and 13 administered Enclomiphene Citrate drug for two weeks. The pharmacodynamics effects of Enclomiphene citrate on total testosterone (TT) were investigated. The Phase I study also assessed the safety and tolerability of Enclomiphene citrate in middle aged subjects.

**Results:** An increase in TT was observed in males with low baseline levels following 14 days of Enclomiphene citrate. The mean increase in TT ranged from 147 ng/dL to 339 ng/dL and results in an increase into the normal range with few excursions above the upper limits. TT increases were greater in men with normal testosterone at baseline. After 14 days of Enclomiphene citrate, mean testosterone levels over a 24-hour sampling period were relatively similar with respect to C<sub>avg</sub>. There was a trough in TT 12 hours after administration. TT levels returned to baseline within 28 days of the last dose of Enclomiphene citrate. No clinically meaningful effects on vital signs, laboratory safety tests or ECG results were noted.

**Conclusions:** Enclomiphene citrate is safe and effective in men with low and normal testosterone and rarely elevates TT above the normal range.

### Introduction

Enclomiphene and zuclophene are structural isomers of Clomiphene citrate, a drug that has demonstrated both estrogenic and anti-estrogenic effects in women [1]. These differential effects are thought to result from different activities of the enclomiphene and zuclophene [2] and a greatly extended half-life of zuclophene [3]. Clomiphene citrate has been used to induce ovulation [4] and also been used in men to raise testosterone [5,6] to reverse anabolic steroid abuse [7] and raise sperm counts in men with no-obstructive azoospermia [8].

Since enclomiphene has demonstrated anti-estrogenic activity and is postulated to normalize the function of the hypothalamic-pituitary-testicular axis observed in men with secondary hypogonadism, the compound may have utility as an alternative approach to raising or normalizing total testosterone (TT) levels in men with testosterone

deficiencies. The increase in serum testosterone beyond the normal range is not without consequences [9,10]. In a recent report [11] where hypogonadal men were treated with injectable, topical and pellet formulations of testosterone, there was a difference in the level of TT and estradiol achieved and a clear difference in TT elicited by the injectable T product but with strong changes on erythrocytosis (changes in hemoglobin concentration and hematocrit). This may be contrasted with the use of Enclomiphene citrate to raise TT in the men with secondary hypogonadism [12-15].
