Optimizing IGF-I for skeletal muscle therapeutics - PMC

Spinal and bulbar muscular atrophy is an X-linked neuromuscular disease caused by CAG repeat expansion in the androgen receptor gene. Patients with this disease have low concentrations of insulin-like growth factor-1 (IGF-1), and studies of overexpression and administration of IGF-1 showed benefit in a transgenic model; thus the IGF-1 pathway presents as a potential treatment target.

Mechanisms of IGF-1-Mediated Regulation of Skeletal Muscle Hypertrophy .

Insulin-like growth factor I (IGF-I) is critical for the growth and development of many tissues. For skeletal muscle, IGF-I coordinates with additional growth factors to promote myoblast proliferation, differentiation, and fiber formation during normal growth as well as during regeneration after injury.

IGF1-LR3 Peptide in Phoenix | Focal Point Vitality

The consequences of these modifications are that IGF-1 LR3 retains the pharmacological activity of IGF-1 as an agonist of the IGF-1 receptor, has very low affinity for the insulin-like growth factor-binding proteins (IGFBPs), and has improved metabolic stability.
